RADIOLOGY

(3) Denotation

CT Whole Abdomen (Plain)

NCCT ABDOMEN

NCCT of the abdomen from domes of diaphragms to the level of pubic symphysis was obtained after oral water administration. Slice thickness of .625 mm/ 5mm were obtained on Discovery 750 HD 64 row spectral scanner.

Almost the entire pancreatic parenchyma in body and tail region is replaced by walled-off necrotic collection (approx. 12 x 8 x 5 cm sized with 6-mm thick walls and internal contents of 9-20 HU in pancreatic and peripancreatic region extending into the lesser sac, gastro-splenic region . The WON is seen abutting the posterior wall of stomach and causing mild extrinsic compression of the stomach lumen. The WON shows heterogenous contents likely proteinaceous/ debris. Only part of head and uncinate process appear spared.

There is associated diffuse peripancreatic fat stranding and omental/mesenteric nodularity in the peripancreatic, omentum, mesentery, retroperitoneum and bilateral perinephric region with attendant mild thickening of bilateral anterior, pararenal, latero-conal fascia (left > right). Calcific specks are seen in the uncinate process seen.

Resultant unopacified collaterals are seen in the splenic hilar, gastroepiploic and peripancreatic locations.

Few subcentimeteric lymph nodes is seen in the upper abdomen.
Liver measures approx. 16 cm in craniocaudal span and shows steatotic attenuation. No evidence of focal lesion or IHBR dilatation is seen.

Gall Bladder is partially distended and shows normal lumen, wall thickness and pericholecystic fat planes. CBD shows normal calibre.

Spleen is normal in size.

Bilateral kidneys show normal size, outline. Adrenals are normal in size and shape.

RADIOLOGY

Abdominal aorta shows atheromatous calcification.

No free fluid is seen.

Impression:

Follow up case of acute necrotizing pancreatitis.

Present scan reveals a large walled-off necrotic collection involving almost entire pancreatic parenchyma. There is not much changes compared to previous CT 14.02.2026
