CLINICAL BIOCHEMISTRY

Test Name	Patient Value	Unit	Reference Range
CRP	62.54	mg/L	0 - 6

Description :
Test interpretation & Clinical Use :
- C-reactive protein (CRP) is an acute phase protein whose concentration rises non-specifically in response to inflammation.
- CRP is seen to increase as a result of the inflammatory process, most notably in response to pneumococcal (bacterial) infection,histolytic disease, and a variety of other disease states.
- CRP is used as a marker or general diagnostic indicator of infections and inflammation, in addition to serving as a monitor of patient response to pharmacological therapy and surgery.

Causes of Increased CRP levels are :
1. Acute Inflammation
2. Rheumatoid Arthritis, Lupus
3. Cardiovascular disease,Atherosclerosis
4. Oral Contraceptives
5. Pregnancy
6. Inflammatory Bowel disease
7. Osteomyelitis
8. Giant cell arteritis

Description : The prothrombin time (PT) and international normalized ratio (INR) are measures of the extrinsic pathway of coagulation.The INR is used only for patients on stable oral anticoagulant therapy. It makes no significant contribution to the diagnosis or treatment of patients whose PT is prolonged for other reasons.
Increased PT times may be due to :
Factor deficiencies(X , II , V , I), Coumadin (warfarin) therapy, Liver Diseases (Bile duct obstruction, Cirrhosis , Hepatitis), Hemmorhagic Disaease of the newborn, DIC, Malabsorption, Fibrinolysis, Vitamin K deficiency.
Interference in PT/INR Alcohol,antibiotics, aspirin, cimetidine,thrombin Inhibitors(Increase PT) Barbiturates, oral contraceptives, Hormone replacement therapy (HRT), and vitamin K (Decrease PT).

Description : Lactate dehydrogenase (LD or LDH) is an enzyme involved in energy production that is found in almost all of the body's cells, with the highest levels found in the cells of the heart, liver, muscles, kidneys, lungs, and in blood cells; bacteria also produce LD. This test measures the level of LD in the blood or sometimes other body fluids.
Blood LD
Only a small amount of LD is usually detectable in the fluid portion of the blood (serum or plasma). LD is released from the cells into the serum when cells are damaged or destroyed. Thus, an LD blood level is a non-specific marker for the presence of tissue damage somewhere in the body. By itself, it cannot be used to identify the underlying cause or

location of the cellular damage. However, it may be used, in conjunction with other blood tests, to help evaluate for and/or monitor conditions that lead to tissue damage, such as liver or blood diseases or cancer.
Fluid LD
Sometimes when there is injury, inflammation, or infection within a specific area of the body, such as the brain, heart or lungs, fluid will accumulate or constituents of the fluid present will change. The level of LD present in the fluid may be useful in determining the cause. For example, LD is typically high in cerebrospinal fluid when an individual has bacterial meningitis. The LD test can also be used, along with other tests, to determine whether fluid accumulation, for example around the heart or lungs or in the abdominal cavity, is due to injury or inflammation (exudate) or due to an imbalance of fluid pressure inside blood vessels and the protein level in blood (transudate). The article on Body Fluid Analysis lists some fluids that may be evaluated using an LD test.

HORMONE

Test Name	Patient Value	Unit	Reference Range
FERRITIN	141.3	ng/ml	Male 25 - 380 Female 15 -150

Description :Ferritin is a protein that contains iron and is the primary form of iron stored inside of cells. The small amount of ferritin that is released and circulates in the blood is a reflection of the total amount of iron stored in the body. This test measures the amount of ferritin in the blood.
Iron is an essential trace element and nutrient that, among other functions, is necessary for the production of healthy red blood cells (RBCs). The body cannot produce iron and must absorb it from the foods we eat or from supplements.
In healthy people, most of the iron absorbed by the body is incorporated into the hemoglobin of red blood cells. Most of the remaining is stored as ferritin or as hemosiderin, with additional small amounts used to produce other proteins such as myoglobin and some enzymes. Ferritin and hemosiderin are present primarily in the liver but also in the bone marrow, spleen, and skeletal muscles.
When the level of iron is insufficient to meet the body's needs, the level of iron in the blood drops, iron stores are depleted and ferritin levels decrease. This may occur because:
Not enough iron is consumed (either foods or supplements) The body is unable to absorb iron from the foods eaten in conditions such as celiac disease There is an increased need for iron such as during pregnancy or childhood, or due to a condition that causes chronic blood loss (e.g., peptic ulcer, colon cancer).
